1. Consider the set H of all non-negative integer solutions to the equation:

$$a_1 + a_2 + a_3 + a_4 + a_5 + a_6 = 30$$

(a) What is the probability that you get the element: (5, 5, 5, 5, 5, 5)? Shoudl we call it like event A so the possibilit that even A occures is equal to the possible outcomes / the total outcomes. Since this is a probability question you need to find the fraction of the possible outcomes over total outcomes.

i. In this case the total outcomes is: $6^{30}$ ( all 30 dice roll has six potential options).

ii. The total possible outcomes is the product of the number of ways to choose 5 dice rolls for that number, given the number of dice rolls left:

$$\binom{30}{5} \cdot \binom{25}{5} \cdot \binom{20}{5} \cdot \binom{15}{5} \cdot \binom{10}{5} \cdot \binom{5}{5}$$

Solution: The possibility that you get the element (5, 5, 5, 5, 5, 5):

$$P(A) = \frac{\binom{30}{5} \cdot \binom{25}{5} \cdot \binom{20}{5} \cdot \binom{15}{5} \cdot \binom{10}{5} \cdot \binom{5}{5}}{6^{30}}$$

(b) What is the probability that at least one of the entries is 0? Event A is the probability that at least one of entries is a 0 So the total probability of all outcomes is again as stated earlier: $6^{30}$. To find the number of ways to have at least one zero entry we use the inclusion exclusion rule starting from choosing oen of the 6 characters to be zero untill all but one was rolled zero times. The representation of the inclusion-exclusion is as follows:

$$\binom{6}{1}5^{30} - \binom{6}{2}4^{30} + \binom{6}{3}3^{30} - \binom{6}{4}2^{30} + \binom{6}{5}1^{30}$$

we use the inclusion exclusion rule to remove the double counted values (give a short exmaple). **Solution: The possibility of event A, that at least one of the entris is a 0:**

$$P(A) = \frac{\binom{6}{1}5^{30} - \binom{6}{2}4^{30} + \binom{6}{3}3^{30} - \binom{6}{4}2^{30} + \binom{6}{5}1^{30}}{6^{30}}$$

(c) What is the probability that one of the entries is exactly 16? Given A is the event that one entry is exactly 16. I'd break this question up into 3 parts.

i. The number of ways to choose 16 rolls out of 30: $\binom{30}{16}$

ii. The chance of one number 16 times: $\frac{1}{6}^{16}$

iii. The change of getting every other number 14 times (the rest of the rolls): $\frac{5}{6}^{14}$

iv. The final factor is the number of

**Solution:**

$$P(A) = \binom{30}{16} \cdot \frac{1}{6}^{16} \cdot \frac{5}{6}^{14}$$

(d) Explain why this is not a uniform random sampling. (Show that the probability of each outcome is not equally likely.) The following problem is not a uniform random sample because the outcomes of two elements have different probabilities so sampling can not be uniform. For example:

i. Given event A = (30, 0, 0, 0, 0, 0)
ii. Given event B = ( 5, 5, 5, 5, 5, 5)

The probability of A, $P(A) = \frac{1}{6}^{30}$ The probability of B, $\frac{30!}{5!^6} \cdot \frac{1}{6}^{30}$

$$P(B) = \frac{30!}{5!^6} \cdot P(A)$$

$$P(B) > P(A)$$

The probability of event B happening is greater than event A thus the sampling is not uniform.

(e) Which elements are the least likely to occur and why? The elements least likely to occur are the ones where only one entry was rolled 30 times. There is only one possible way to roll a 1 or 2 30 times in a row. Other elements can be made with multiple sequences

2. Suppose you are at a casino and there are three slot machines. You know that two slot machines each win with probability 0.5, and the other wins with a probability of 0.9. You pick one of the slot machines (equally at random) and you play 8 games and win them all.

(a) What is the probability that you are at the slot machine that wins with probability of 0.9? To find the probability that you were using the machine with a winning percentage of 0.9 given you won 8 straight games we will define the following:

i. Event N is you picked 0.9 slot machine
ii. Event W is you won 8 straight games

Now we need to find the probability $P(N|W)$. Using Bayes Theorem we can rewrite the equation into values that we know

$$P(N|W) = \frac{P(W|N)P(N)}{P(W)}$$

$$P(N|W) = \frac{(0.9)^8 \cdot \frac{1}{3}}{\frac{1}{3} \cdot (0.5^8 + 0.5^8 + 0.9^8)}$$

(b) If you decide to stay at the same slot machine (after winning 8 games), what is the probability that your next game results in a win?
